

Ostracods from the Upper Jurassic (Oxfordian–Tithonian) of southern Germany

U. SCHUDACK & M. E. SCHUDACK

Institut für Paläontologie, Freie Universität Berlin, Malteserstr. 74–100, Haus D, 12249 Berlin, Germany (e-mail: schudack@zedat.fu-berlin.de).

ABSTRACT – At present the ostracod faunas from the Upper Jurassic of southern Germany are incompletely known due to the absence of detailed studies. This preliminary systematic investigation has yielded 46 species from 25 genera, of which 23 species are left in open nomenclature, while 4 are new species: *Bythoceratina (Praebrythoceratina) danuvensis*, *Nemoceratina (Pariceratina) urlichsi*, *Pokornyopsis punctata* and *Quasihermanites spiralus*. Diversity increases through the late Jurassic with 16 species in the Oxfordian, 19 species in the Kimmeridgian, and 23 species in the Tithonian. Endemism is lowest in the Oxfordian, while highest in the Kimmeridgian. *J. Micropalaeontol.* 19:(2) 97–112, December 2000.

INTRODUCTION

With few exceptions (e.g. Glashoff, 1964; Oertli, 1965), the ostracod faunas from the Upper Jurassic of southern Germany (Fig. 1) have not yet been studied in detail, possibly due to the rarity and often poorly preserved nature of the material. Ammonite faunas are, however, abundant and have been used for chronostratigraphy. This study looked at: (i) the pattern and diversification of ostracod biogeography, (ii) the possible correlation of ammonite biozones from southern Germany with ostracod biozones in northern Germany; and (iii) contributions to the palaeoclimatic history of the late Jurassic in Central Europe. For these investigations, which are based on a larger set of data including species which have been reported by other authors, see Schudack & Schudack (1997), Schudack (1999) and a short summary in the conclusions in this paper.

Here, a provisional inventory and systematic investigation of the ostracod fauna, systematic descriptions of four new species, several recombinations of taxa, some comments on other taxonomical problems, and the stratigraphical ranges in southern Germany are given, as well as figures of the species. Another new species, *Palaeocytheridea groissi*, has already been described in Schudack (1997).

MATERIAL

The material studied in this paper has been gathered from a number of sources. Samples from the Franconian Jurassic (Fig. 1) have been provided by Dr Schairer (Munich) and Professor Groiss (Erlangen). A total of 113 samples from 25 sections (summarized to 18 areas in Fig. 2) have yielded the ostracods

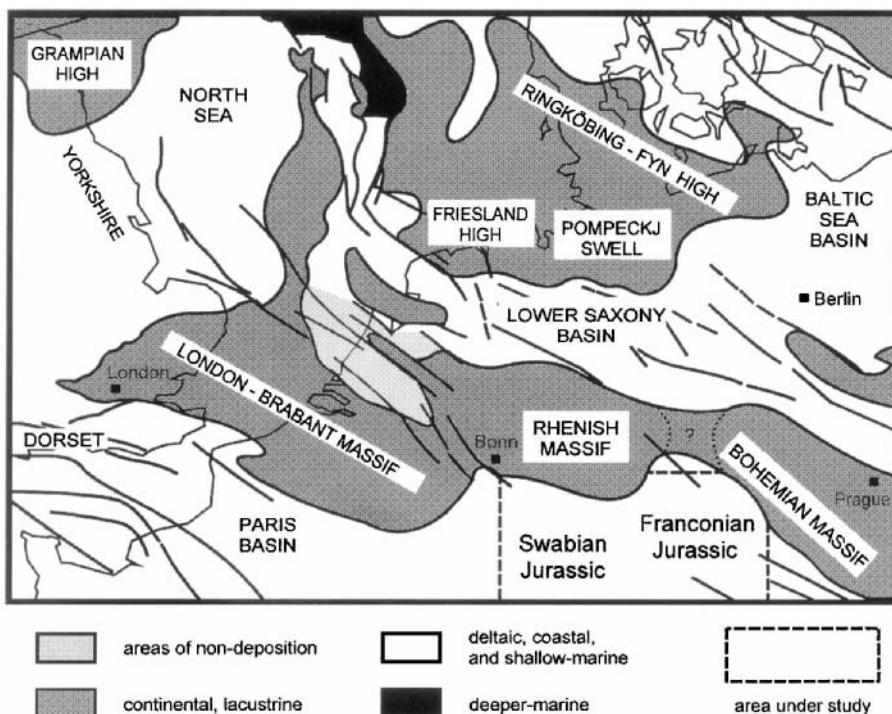

Fig. 1. Palaeogeography of the Kimmeridgian and Tithonian in Central Europe (redrawn after Ziegler, 1990) and position of the study area (Swabian and Franconian Jurassic) between the Central European Swell (Rhenish and Bohemian massifs) to the north and the Tethys to the south.

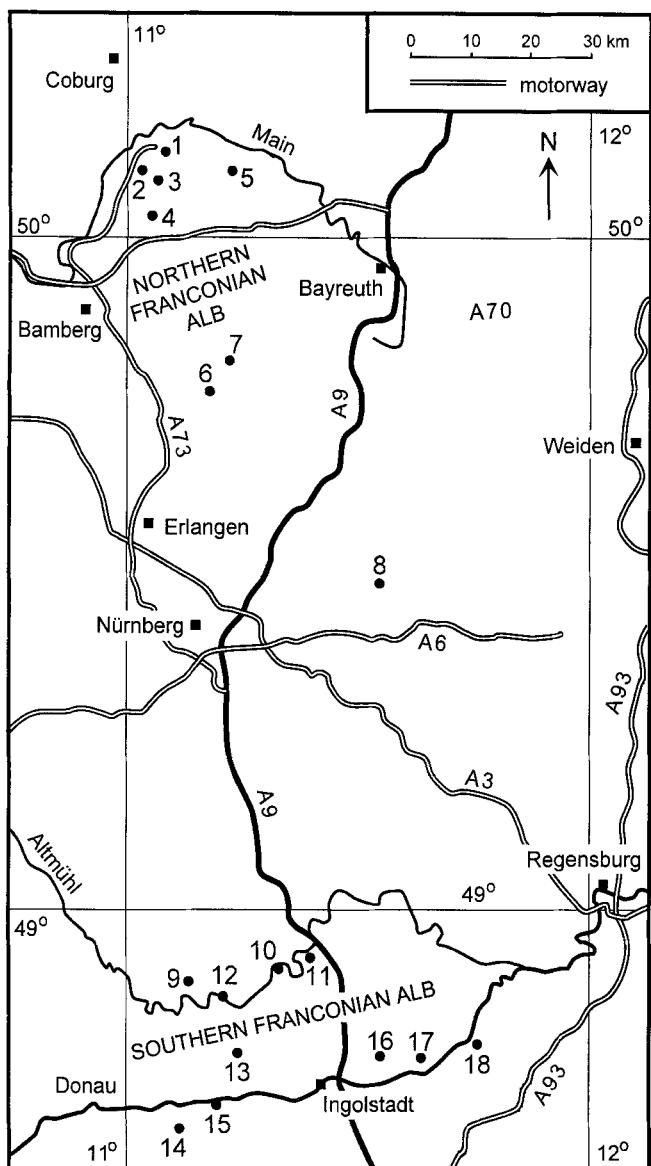

Fig. 2. Position of sampled localities in the Franconian Jurassic (see Fig. 1). 1, SE Lichtenfels (Schwabthal, Lahmer Steige, Attendorfer Steige, Dörrwasserlos); 2, area near Staffelstein (Spitzberg, Staffelberg); 3, Uetzing; 4, Dornig/Oberküps; 5, Weismain; 6, Ebermannstadt/Rüsselbach; 7, Schauertal N Streitberg; 8, Hartmannshof; 9, Sappenfeld; 10, Pfalzpaint; 11, Kipfenberg; 12, Eichstätt; 13, Untermöckenlohe; 14, Unterhausen; 15, Neuburg/Donau; 16, Demling; 17, Ober/Unterhartheim; 18, Haderfleck (Neustadt/Donau).

considered in this paper. Their stratigraphical ranges are from the Oxfordian into the Middle Tithonian (Fig. 3). Most of the material from the Swabian Jurassic (Fig. 1) comprises picked samples donated by Dr Urlich (Stuttgart) and from our own field work in the southernmost part of the Swabian Alb mountains. Here, a total of 25 samples from 9 sections (summarized to 8 areas in Fig. 4), have yielded ostracods, ranging from the Oxfordian into the early Tithonian (Fig. 5). If not noted otherwise, the material is housed at the Institute of

Paleontology of the Free University of Berlin.

OSTRACODS FROM THE UPPER JURASSIC OF SOUTHERN GERMANY

This preliminary account of the Upper Jurassic ostracods from southern Germany has identified 46 species from 25 genera, of which 23 species are left in open nomenclature. Their stratigraphical ranges in southern Germany are shown in Fig. 6. A general increase in diversity through the Upper Jurassic is evident, with 16 species occurring in the Oxfordian, 19 species in the Kimmeridgian and 23 species in the Tithonian. The relative age of each of the ostracod-bearing layers has been determined on the basis of the well-established ammonite biozonation which has been studied in southern Germany since the last century (for summaries and lists of older literature see Zeiss (1977), Ziegler (1977), Dietl & Schweigert (1995), or Schweigert & Callomon (1997)).

All species are figured on Plates 1–5, whereas in the systematics section only those taxa presented as a new species or requiring more discussion have been described.

SYSTEMATIC DESCRIPTIONS OF NEW SPECIES

Order **Podocopida** Müller, 1894

Suborder **Platycopina** Sars, 1866

Family **Cytherellidae** Sars, 1866

Genus **Cytherelloidea** Alexander, 1929

'Formenkreis' of *Cytherelloidea weberi/paraweberi/tripartita* (Pl. 1, figs 4–7)

Within this 'Formenkreis', two groups of species are distinguished: *Cytherelloidea* gr. *weberi* Steghaus, 1951 and *C. gr. tripartita* Glashoff, 1964. The *weberi* group includes the individuals usually described as *C. weberi* or *C. paraweberi*, two species of which are considered to be synonymous (Schudack, 1994). In this group, the peripheral rib extends subparallel to the valve margins, dorsally it may be slightly undulated, while anteroventrally and/or anterodorsally it may be interrupted. The valve is either smooth or reticulated. A median rib and two knob-like protuberances occur immediately in front of the posterior margin in the female carapaces.

Cytherelloidea gr. *tripartita* Glashoff, 1964 includes individuals with the dorsal part of the rib subdividing into three oblique fragments, situated staggered in succession. It also includes those forms, like the Czech species '*Cytherelloidea* aff. *mandelstami*' Pokorný, 1973' in which the dorsal rib turns, with a pronounced angle, at half length of the carapace to the anterior, where it runs a distance under the frontal rib. Many of these ostracods possess a subdorsal rib (*sensu* Pokorný), which is situated in case of reduction of the posterior part of the dorsal rib instead of the third fragment of the interrupted dorsal rib. Species figured and described as '*weberi*' or '*paraweberi*' by Oertli (1959, pl. 2, figs 28, 29), Donze (1960, pl. 1, fig. 5) and Depèche (1985, pl. 34, fig. 2) also belong to this 'Formenkreis'.

All individuals recorded from southern Germany belong to *Cytherelloidea* gr. *tripartita*.

Suborder **Podocopina** Sars, 1866

Superfamily **Cytheracea** Baird, 1850

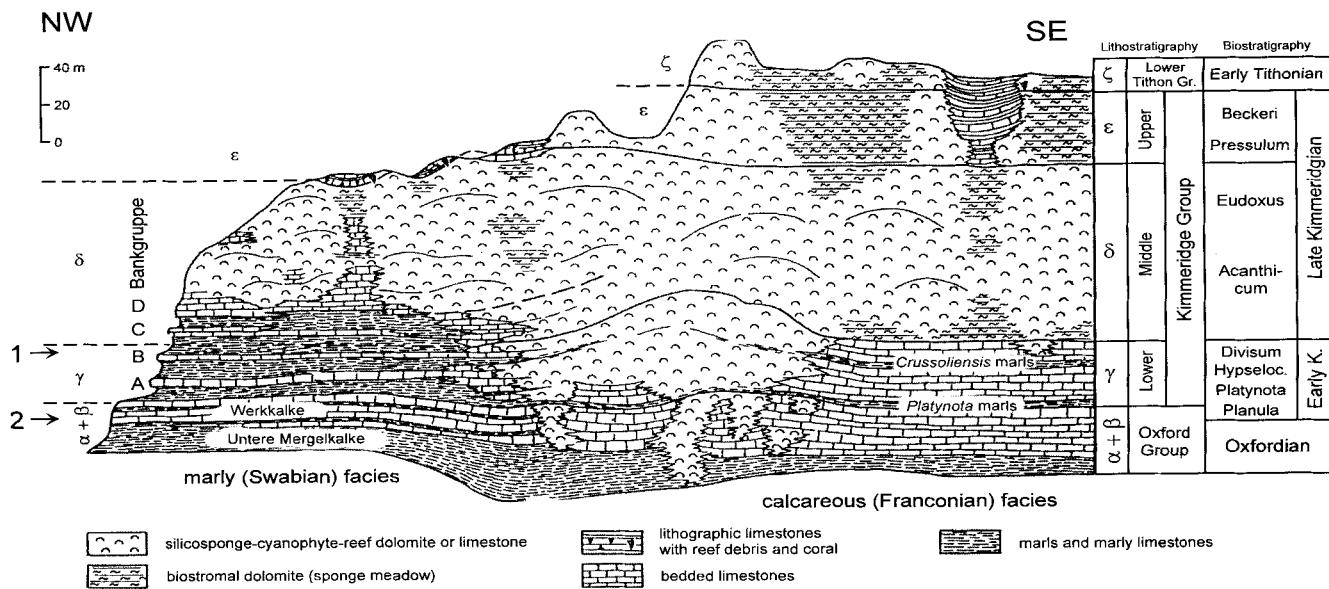

Fig. 3. Generalized litho- and biostratigraphy of the northern Franconian Upper Jurassic (Fig. 2), redrawn and modified after Zeiss (1977) and Meyer & Schmidt-Kaler (1996); position of the Oxfordian/Kimmeridgian boundary after Schweigert & Callomon (1997), with stratigraphical positions of type horizons of *Bythoceratina (Praebythoceratina) danuvensis* n. sp. (1) and *Pokornyopsis punctata* n. sp. (2). On the southern Franconian Alb (Fig. 2), a slightly different Jurassic facies reaches up into the Middle Tithonian (Neuburger Bankkalke).

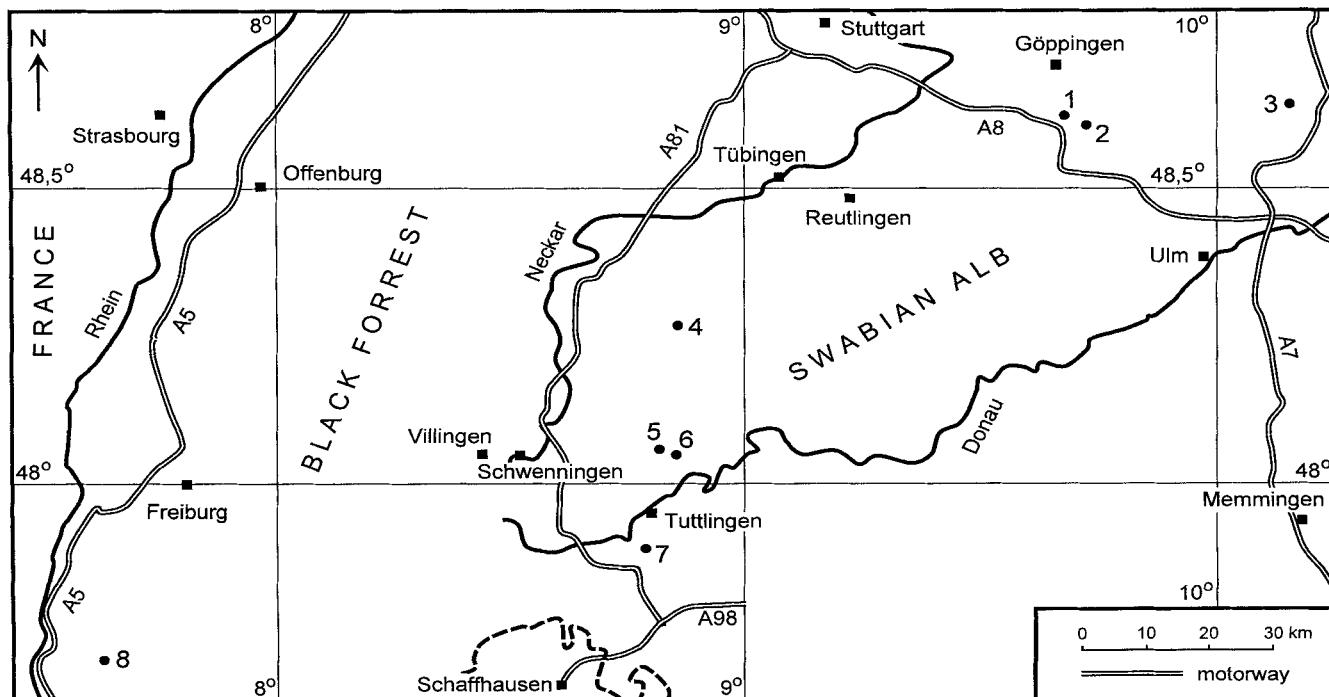

Fig. 4. Position of sampled localities in the Swabian Jurassic (see Fig. 1). 1, Auendorf; 2, Reichenbach im Täle; 3, Bolheim; 4, Irrenberg and Lochenpass near Balingen; 5, Aggenhausen W Mahlstetten; 6, Mahlstetten; 7, railway cutting north of Engen; 8, Kandern.

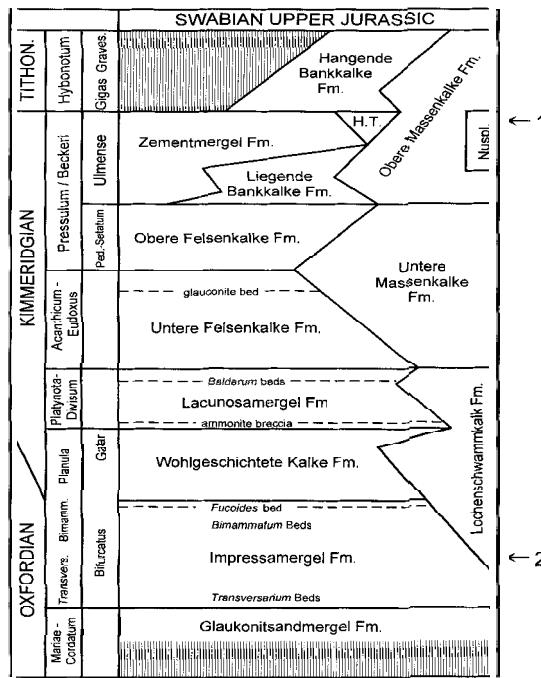

Fig. 5. Generalized litho- and biostratigraphy of the Swabian Upper Jurassic (redrawn after Dietl & Schweigert, 1995) with stratigraphical positions of type horizons of *Quasithermanites spiralus* n. sp. (1) and *Nemoceratina (Pariceratina) urlichii* n. sp. (2). Abbreviations: HT, Hattinger Trümmerkalke Facies; Nuspl., Nusplinger Plattenkalke Facies.

Family **Bythocytheridae** Sars, 1926
 Subfamily **Bythocytherinae** Sars, 1926
 Tribus **Bythoceratini** Gründel & Kozur, 1972
 Genus **Bythoceratina** Hornbrook, 1952
 Subgenus **Praebrythoceratina** Gründel & Kozur, 1972

Bythoceratina (*Praebrythoceratina*) danuvensis n. sp.
 (Pl. 1, figs 14–16)

- cf. 1973 *Bythoceratina* n. sp. A Pokorny: 95, pl. 12, fig. 4
 ? 1975 *Monoceratina* sp. B Bate: 180, pl. 2, fig. 3.
 1987 *Bythoceratina (*Praebrythoceratina*)* sp. A Lord *et al.*: 591, fig. 8/1.
 1987 *Monoceratina* cf. sp. B Bate, 1975; Rosenfeld *et al.*: 239, pl. 1, fig. 13.

Derivation of name. From the largest river (Donau/Danube) in Southern Germany where the species is frequent in many regions.

Diagnosis. A species of the genus *Bythoceratina* (subgenus *Praebrythoceratina*) with the following distinctive features: carapace elongate, dorsal and ventral margins subparallel. Median furrow in most cases is limited by a marginal rib, often with knobs at its anterior border. Valve surface carries pentagonal pits, arranged in a characteristical manner.

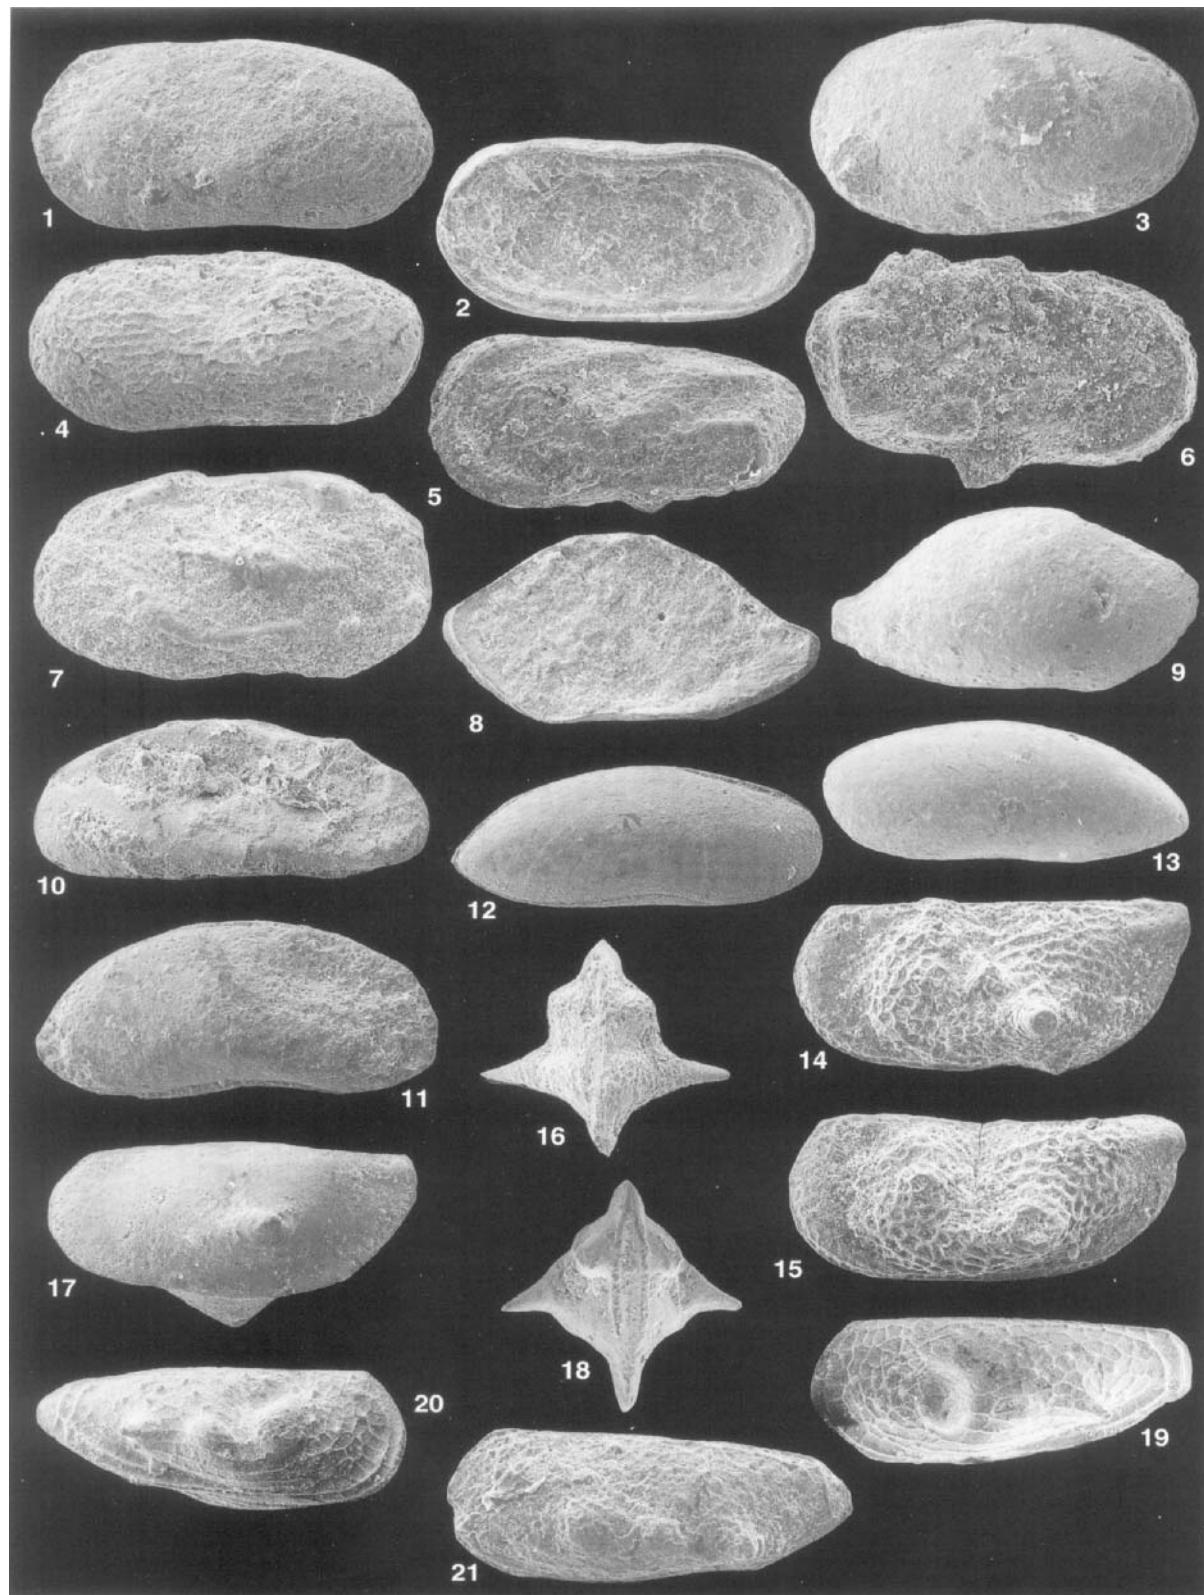

Types. Holotype, left valve (Plate 1, fig. 14). Paratypes, about 50 specimens. Staatliches Museum für Naturkunde Stuttgart, Inventory-Nr. 75106/1.

Locality & horizon. Dornig, SE Staffelstein, northern Franconian Alb, Bavaria, TK 25 sheet 5932 Uetzing (Fig. 2). Sample Groiss 181. Lower Kimmeridgian, Malm gamma, 1.3 m above ‘Bankgruppe B’ (Fig. 3).

Description. The carapaces are elongated-rhomoid, the dorsal and ventral borders are subparallel. The ventral margin is sinuous, posteroventral margin convex, extending into an inclined, slightly elongated caudal process, situated postero-dorsally. The anterior margin is broadly rounded, similar to the posterior margin, and possesses a marked selavage. The lateral surfaces are unevenly inflated, overlapping the ventral margin centrally and with a prominent spine postero-ventrally. The median furrow is broad and low, sometimes smaller and deeper and in most cases rampart-like, with one knob immediately above mid-height and another one situated diagonally across in

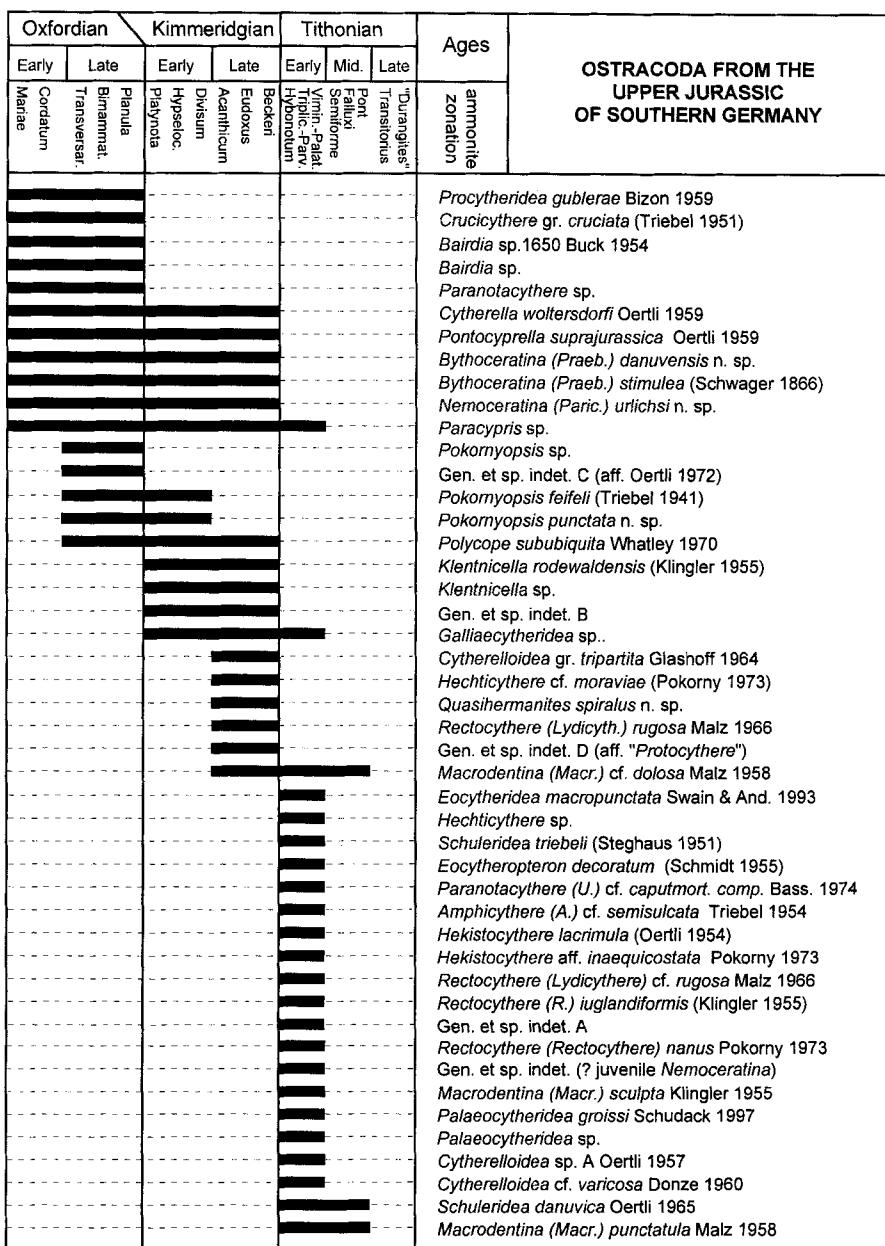

Fig. 6. Stratigraphical ranges of ostracode species in the Upper Jurassic of southern Germany. The ammonite zonation given here is a composite for Southern Germany after Zeiss (1977), Dietl & Schweigert, (1995) and Schweigert & Callomon (1997). All species listed here are figured on Plates 1–5, whereas in the section on ‘systematics’ only those taxa which are new species or which require more discussion have been described.

front of it. Occasionally, these knobs are very small. The valve surfaces are covered with pentagonal pits, arranged in rows along the marginal surface and near the ventral margin. They extend around the root of the spine and the median furrow and reflect the sculpture of the valves. In dorsal view, the carapaces are arrow-shaped, the anterior and posterior margins being pronounced keel-like. Eye-tubercles and lateral spines are well pronounced. Internal details not observed.

Dimensions. Length 0.50–0.57 mm, height 0.23–0.26 mm.

Occurrence. In southern Germany this taxon occurs in the Oxfordian and Kimmeridgian. Pokorny (1973) described this species from the Kimmeridgian of the lower Klentnice Formation in Southern Moravia (see Schudack & Schudack, 1997 concerning the revised age of this formation). Bate (1975) records this species from the Middle Callovian of Tanzania, Lord *et al.* (1987) from the *autissiodorensis* Zone (Kimmeridgian) of the Volga Basin and Rosenfeld *et al.* (1987) from the Oxfordian Kidod Formation of Israel.

Remarks. The species shows strong similarities to *Bythoceratina* (*Praebrythoceratina*) *scrobiculata* (Triebel & Bartenstein, 1938), from which it is probably derived. Both species are distinguished by the inflation of the valve selvages, the form of the caudal process, and the reticulate surface ornamentation.

Genus *Nemoceratina* Gründel & Kozur in Kozur, 1971

Subgenus *Pariceratina* Gründel & Kozur, 1972

Nemoceratina (*Pariceratina*) *urlichi* n. sp.

(Pl. 1, figs 19–21)

Derivation of name. In honour of Dr M. Urlich, Museum of Natural History, Stuttgart, Germany, who kindly made the material available.

Diagnosis. A species of the genus *Nemoceratina* (subgenus *Pariceratina*) with the following characteristics. Keel-like prominences are seen on the anterior and posterior margins. The valve surfaces are reticulate, covered with small pointed spines located on the angles of the sculptural meshes. There is no anterodorsal lobe and there are three knobs parallel to the ventral border.

Types. Holotype, left valve (Plate 1, fig. 19). From Coll. K. Feifel, 1947. Paratypes, 5 specimens. Staatliches Museum für Naturkunde Stuttgart, Inventory-Nr. 75115/1.

Locality & horizon. Reichenbach im Täle, Swabian Alb, Baden-Württemberg, TK 25 sheet 7324 Geislingen an der Steige West (Fig. 4). Upper Oxfordian, *bifurcatus* subzone, Impressamergel (Fig. 5).

Description. In lateral view, the carapaces are trapezoidally elongated, with their greatest height at the anterior cardinal angle. The dorsal margin is straight and only slightly inclined to the pronounced posterior cardinal angle. The posterior margin is rounded subtriangular, with a large caudal process situated above mid-height. The transition to the ventral border is rounded, the latter being overlapped by the slight inflation of the lateral surfaces. The anterior margin is broadly rounded. The valve surface comprises a network of fine meshes, which join in the marginal areas to form small ribs. Finely pointed spines or papillae are irregularly distributed at the angles of these meshes. Anterior and posterior borders possess keel-like prominences without any sculpture. In front of the caudal process, a distinct furrow is developed, underlining the posterior margin more strongly. Immediately above the median part of the ventral border, three knobs are situated in a subparallel line. The anterior knob, which lies at the base of a small sulcus, is the largest. Both the anterior and median knob are smooth, while the posterior knob terminates into a small spine.

Dimensions. Length 0.52–0.64 mm, height 0.21–0.27 mm.

Occurrence. Southern Germany, Oxfordian to Kimmeridgian.

Remarks. *Nemoceratina* (*Pariceratina*) *urlichi* n. sp. is considered to be closely related to *Nemoceratina* (P.) sp. Depèche (1985: 135, pl. 31/14), but differs in the development of the ventral knobs and the posterior end. The anterior margin is rounded and narrower, and the reticulation is less evident. Further research is necessary to show ancestral relationships with the Bathonian specimens from Normandy.

Family *Cytherettidae* Triebel, 1952

Subfamily *Palaeocytherideinae* Ljubimova, 1955

Tribus *Hechticytherini* Gründel, 1974

Genus *Hechticythere* Gründel, 1974

Hechticythere cf. *moraviae* (Pokorny, 1973)

(Pl. 2, fig. 2)

Remarks. Pokorny (1973) described this species as part of the subgenus *Valendocythere*, which was regarded as a genus by Gründel (1974a,b). However, the only criterion for *Valendocythere* would be the bulb-like thickening of the ventral rib posteriorly. Neither a decomposition of the lateral ribs into single lobes nor a reduction of them, nor a development of a median lobe or a reduction of the dorsal rib is observed in our material and so the species is regarded as belonging to the genus *Hechticythere* Gründel, 1974.

Family *Cytheruridae* Müller, 1894

Subfamily *Cytherurinae* Müller, 1894

Genus *Paranotacythere* Bassiouni, 1974

Subgenus *Unicosta* Bassiouni, 1974

Paranotacythere (*Unicosta*) cf. *caputmortuum compactum*

Bassiouni, 1974

(Pl. 3, figs 3–4)

1974 *Paranotacythere* (*Unicosta*) *caputmortuum compactum* Bassiouni: pl. 13, figs 11–12.

Occurrence. Lower Tithonian of southern Germany. Couches à *gigas*, Lower Tithonian of France.

Remarks. Only two poorly preserved valves have been recovered. Both specimens are placed into *P. caputmortuum* s. l. because of the following characters. The presence of nodes anteroventrally and on the lateral surfaces posteriorly behind the median furrow are distinctive as is the ala-like projection of the ventral rib posteriorly. The valves are closely related to the species described by Bassiouni (1974: pl. 13, figs 11–12) as *P. caputmortuum* cf. *compactum* from the Ile d'Oléron (France).

Family *Progonocytheridae* Sylvester-Bradley, 1948

Genus *Hekistocythere* Bate, 1969

Hekistocythere lacrimula (Oertli, 1959)

(Pl. 3, fig. 9)

1959 *Cytherura*? *lacrimula* Oertli: 29–30, pl. 4, figs 107–111.

1963 *Cytherura*? *lacrimula* Oertli: Oertli: pl. 38, fig. 1c.

1990 *Metacytheropteron elegans* Oertli; Zihrl: 78, pl. 4, fig. 41.

1995 'Cytherura' *lacrimula* Oertli, 1959; Weiss: 149–150, pl. 8, figs 3–4

Occurrence. Lower Tithonian of southern Germany, Upper Oxfordian to Lower Kimmeridgian of Switzerland and north-western Germany

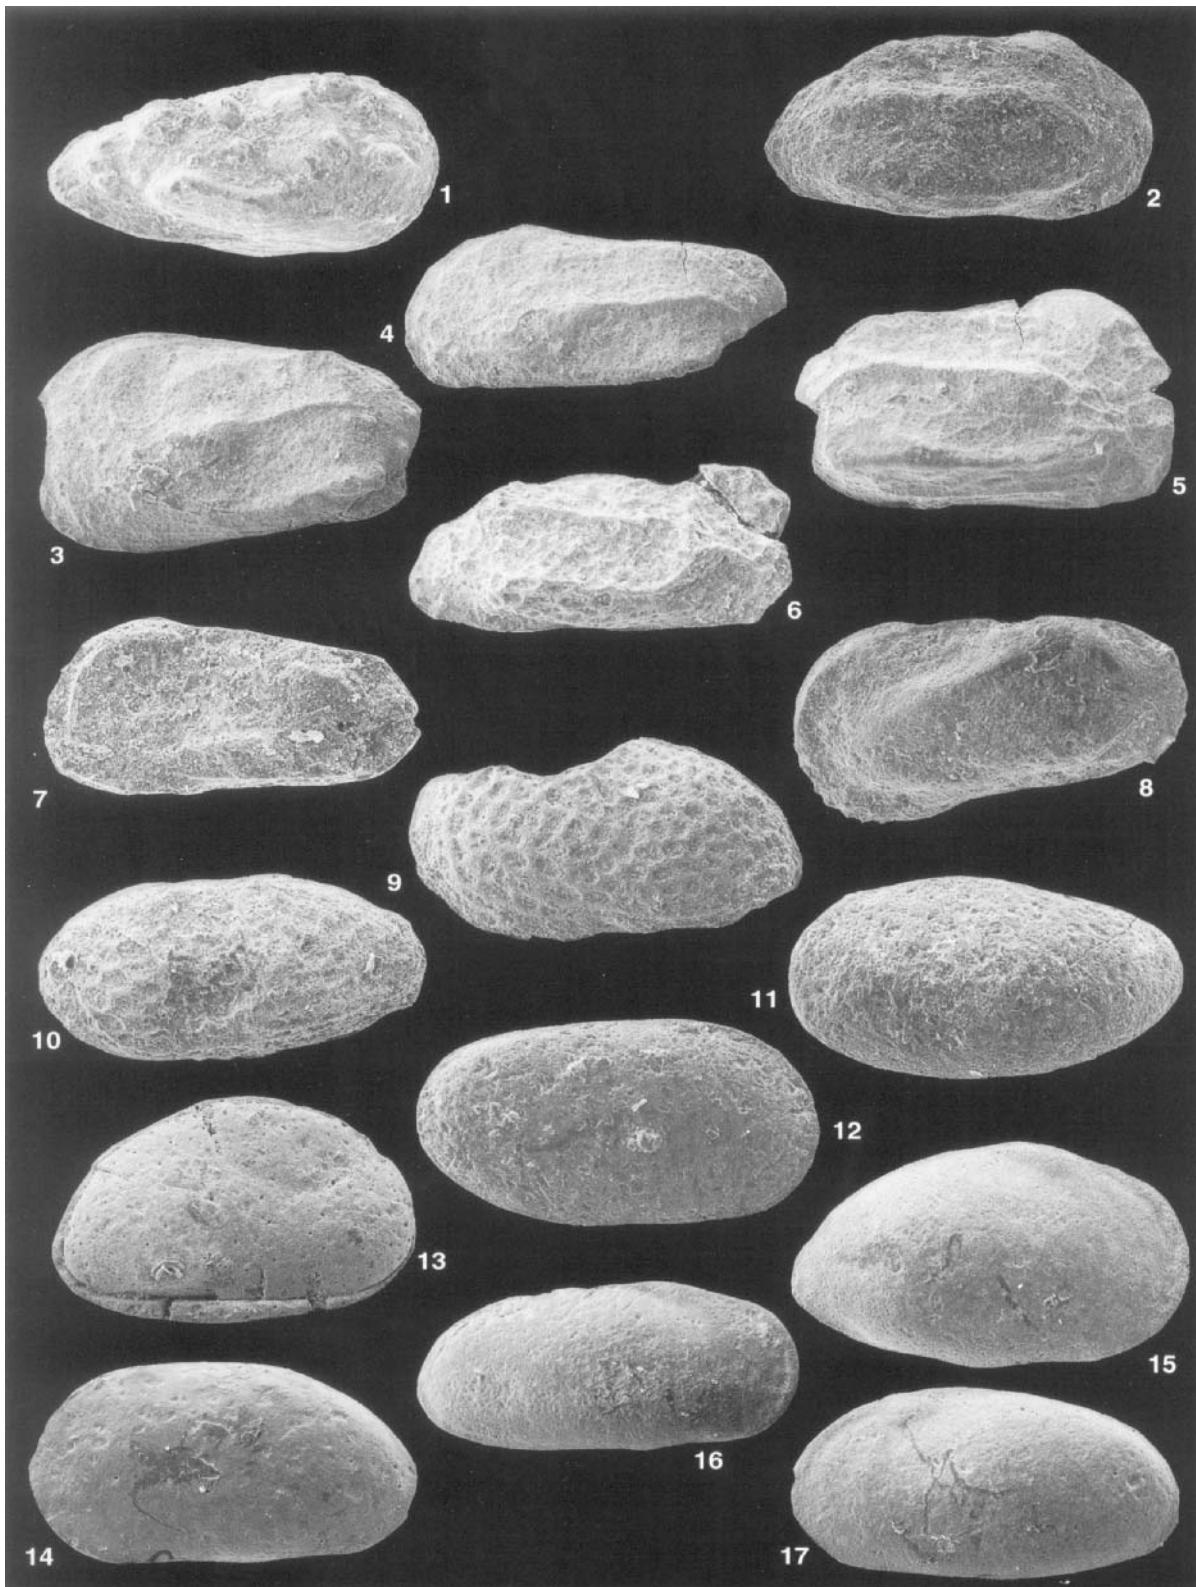

Remarks. The species, which was questionably assigned to *Cytherura* Sars, 1866 by Oertli (1959), is now placed into *Hekistocythere* Bate, 1969 because of the identical lophodont hinge, the general outline, and the corresponding marginal structures.

Hekistocythere aff. *inaequicosta* Pokorny, 1973

(Pl. 3, figs 10–11)

Occurrence. Lower Tithonian of southern Germany.

Remarks. Only a few specimens have been recovered. The taxon

possesses irregular broad crests and intercalated reticulate pits. The specimens are considered to be closely related to *Hekistocythere inaequicosta* Pokorny, 1973 from the Kimmeridgian of southern Moravia which were re-identified by Witte & Lissenberg (1994) in the Upper Kimmeridgian/Lower Portlandian of the North Sea Graben of the Netherlands. However, the southern German species differ from the taxon in having a more differentiated pattern of ornamentation.

Genus *Quasihermanites* Gründel, 1964

Quasihermanites spiralus n. sp.

(Pl. 4, figs 6–7)

Derivation of name. From the spiral arrangement of the sculptural ribs.

Diagnosis. A species of the genus *Quasihermanites* Gründel, 1964, in which the ribs are arranged in a rectangular-formed spiral.

Types. Holotype, left valve (Pl. 4, fig. 7). Paratypes, 3 specimens. Institut für Paläontologie FU Berlin, Inventory Nr. MT 1997-1.

Locality & horizon. Talmühle 2 km north of Engen, on the Tuttlingen-Singen railway, southern Swabian Alb, Baden-Württemberg, TK 25 sheet 8118 Engen (Fig. 4). Sample SD 22 of our 1995 field campaign. Marl at the base of Hattinger Trümmerkalke Member (base of outcrop), uppermost Kimmeridgian (uppermost *pressulum/beckeri* Zone, Fig. 5).

Description. Lateral view of the carapaces subrectangular, with the greatest height at the well-rounded anterior cardinal angle. Elongated eye-tubercle developed beneath the angle. The dorsal and ventral margins are straight and converge towards the posterior. Ventral margin is overlapped by the lateral surfaces in its median part. Posterior margin narrowly rounded, somewhat keel-like pronounced from the lateral surfaces like the more thickened anterior one. The sculpture comprises a series of ribs arranged in a rectangular-formed spiral. The dorsal rib, which is characteristic of the genus, commences beneath the eye-tubercle, extending above the dorsal margin mid-length, with its apex situated in the posterior third. In the posterior third of the valve the dorsal rib extends vertically, joining the ventral rib at 1/4 carapace height. This transition is variable and not always

absolutely evident. The ventral rib is convex and joins the anterior rib, which extends subparallel to the anterior margin to the eye spot, arcuatedly. The eye spot is linked with the dorsal rib by a small crest. At the origin of the dorsal rib, or immediately beneath it, a slightly undulating horizontal median rib occurs situated at about 2/3 carapace-height. Between the lateral ribs, the valve surface is reticulate. In dorsal view, the carapaces are rectangular, the anterior and posterior margins projected keel-like, the dorsal rim is evident. No internal details are observed, due to the material only comprising carapaces. This would be interesting with regard to the statement of Pokorny (1973), whose species *Quasihermanites bicarinatus moravicus* differs from *Q. bicarinatus* Gründel, 1964 and *Q. caistorensis* (Kaye, 1965) only by the terminal elements of the merodont hinge. These are crenulated in the Moravian form and smooth in the two younger species from the Middle Hauterivian to Lower Barremian of England and Lower Hauterivian of Germany.

Dimensions. Length 0.46–0.48 mm, height 0.26–0.29 mm.

Remarks. *Quasihermanites spiralus* n. sp. differs from the closely related species *Q. bicarinatus* Gründel, 1964, *Q. caistorensis* (Kaye, 1965) and *Q. bicarinatus moravicus* Pokorny, 1973 by the spiral arrangement of its lateral ribs.

Family *Trachyleberididae* Sylvester-Bradley, 1948

Subfamily *Neurocytherinae* Gründel, 1975

Genus *Crucicythere* Malz, 1975

Crucicythere gr. *cruciata* (Triebel, 1951)

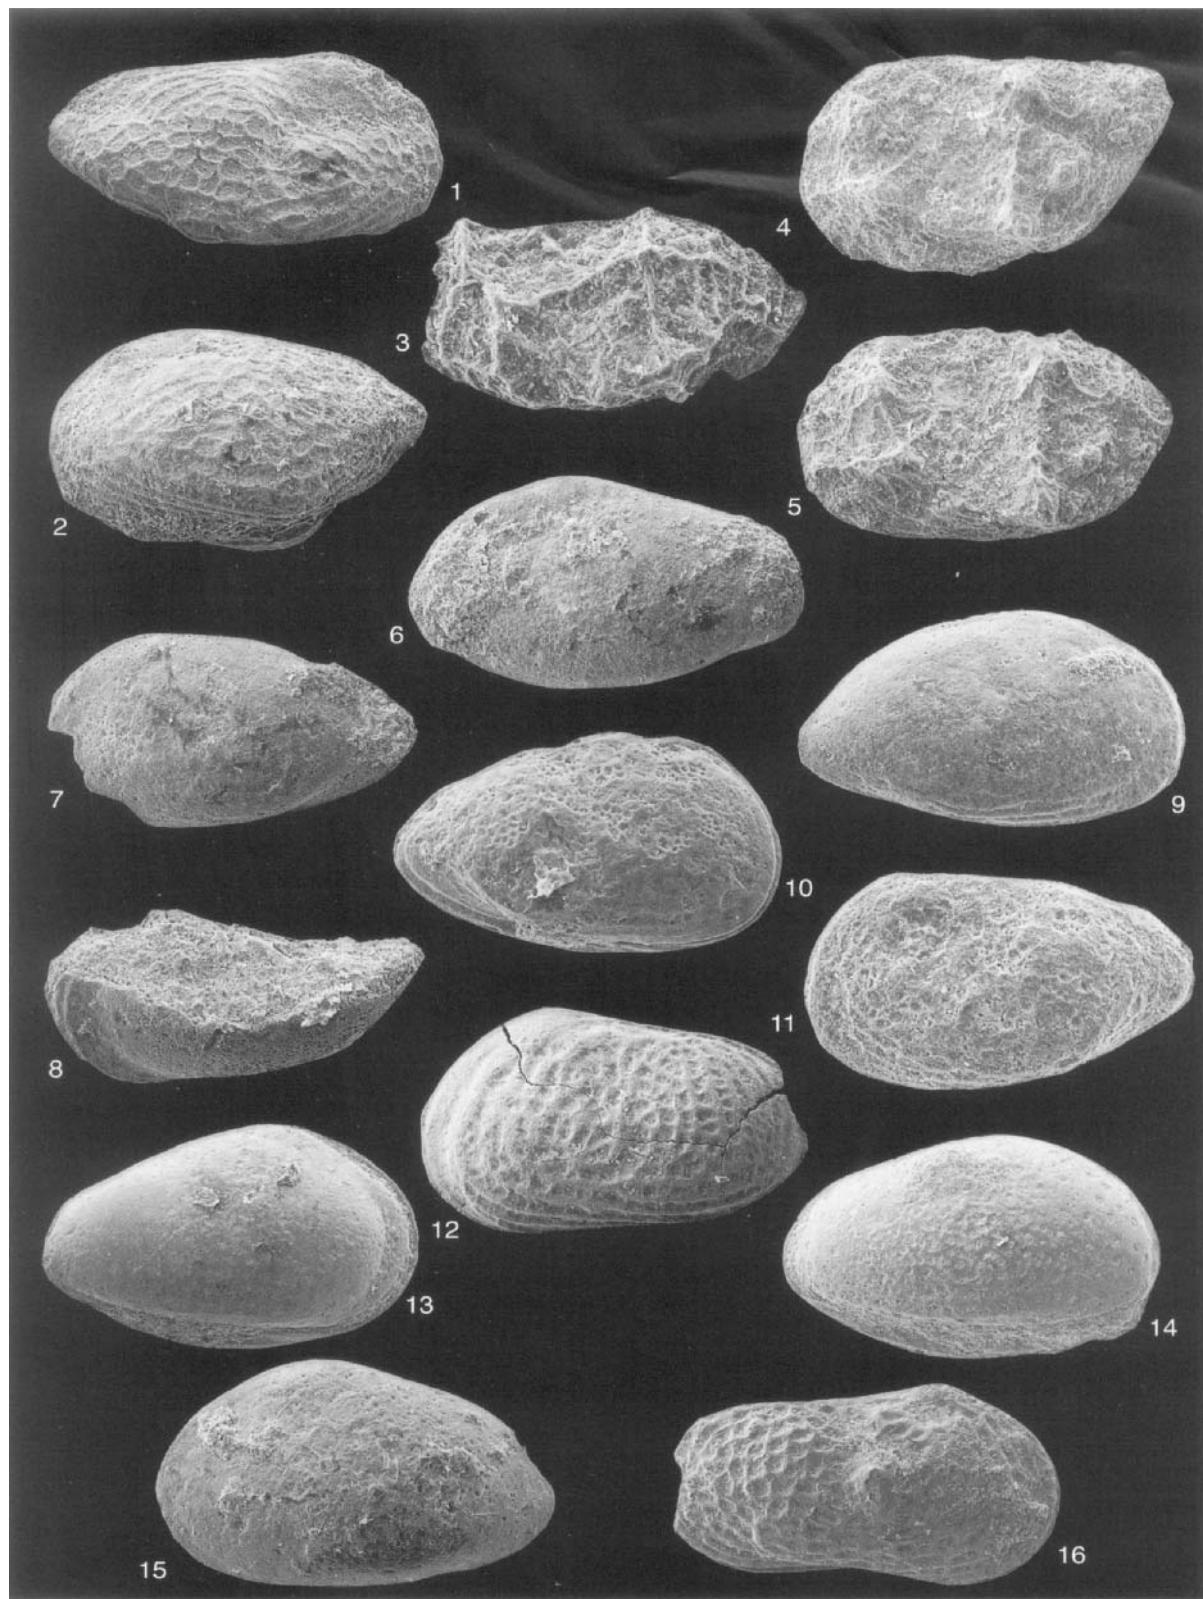

(Pl. 4, figs 14–17)

Occurrence. Uppermost Callovian to Oxfordian of southern Germany.

Remarks. The specimens occurring in southern Germany can be assigned to *Crucicythere cruciata* (Triebel, 1951), but classification to one of the subspecies of Lutze (1960) is difficult. A close relationship to *C. c. intermedia* (Lutze, 1960) is evident, but in this subspecies the vertical ribs extend straight upwards from the median rib, whereas they are much more oblique in the south German specimens. *C. c. oxfordiana* (Lutze, 1960), is the most similar subspecies, but lacks the vertical ribs in the posterior intercostal field. In addition, it has reduced the frontal rib in its

Explanation of Plate 2

lower part. Pokorny (1973) has also described a form belonging to this group (*Lophocythere (Neurocythere) cruciata* Triebel, 1951, aff. *oxfordiana* Lutze, 1960), which shows a similar but somewhat different pattern of ornamentation and cannot be assigned to one of these subspecies or to the southern German specimens. Obviously, this group has undergone a differentiated evolution in the various areas of its distribution. For the classification of the nominate-species into the genus *Crucicythere* Malz, 1975 see Schudack (1994, pp. 100–101).

Order Myodocopida Sars, 1866

Suborder Halocypridina Dana, 1852

Superfamily Thaumatoxypidacea Müller, 1906

Family Thaumatoxypididae Müller, 1906

Genus *Pokornyopsis* Kozur, 1974

***Pokornyopsis feifeli* (Triebel, 1941)**

(Pl. 5, figs 1–3)

Occurrence. Upper Oxfordian and Lower Kimmeridgian of southern Germany.

Remarks. We follow Kornicker & Sohn (1976) and Neale (1983), who assign the genus to the subfamily Thaumatoxypidacea Müller, 1906. We agree with both authors, who do not see any necessity to deviate from a classification of the genus in the Myodocopida, as proposed by Kozur (1974). Based upon a detailed study on diverse material, Kornicker & Sohn (1976) re-orientated the valves, so that the two protuberances get into an anteroventral position.

***Pokornyopsis punctata* n. sp.**

(Pl. 5, figs 4–8)

Derivation of name. After the regularly punctated surface of the valves.

Diagnosis. A species with the characteristics of the genus *Pokornyopsis* and a lateral surface covered with a network of mostly rounded meshes, which form a regular pattern all over the valves.

Types. Holotype, left valve (Plate 5, fig. 4). Paratypes, 12 specimens. Staatliches Museum für Naturkunde Stuttgart, Inventory-Nr. 75111/1-3.

Locality & horizon. Schauertal N Streitberg, near Forchheim, northern Franconian Alb, Bavaria, TK 25 sheet 6133 Muggendorf (Fig. 2). Schwamm-Mergel, *bimammatum* Zone, Upper Oxfordian, Malm beta (Fig. 3).

Description. In lateral view, the valves are roundly-oval in shape, with a straight dorsal, a rounded posterior, and a broadly rounded anterior margin. The antero-dorsal margin is evenly rounded. Two spines occur at approximately midheight and anteroventrally. They can be very long (Plate 5, fig. 6), but are often broken. The upper spine is directed forwards/upwards, whereas the lower spine turns forwards/downwards. Between these spines, the anterior margin is straight or slightly concave. Posterodorsally, there is a third spine, and a slight depression immediately in front of it.

The lateral surface is covered with roundly pentagonal meshes, which are arranged subparallel to the margins and appear to be somewhat disordered centrally over the valves where the central muscle scars are situated. Although the meshes are arranged in rows, there is no impression of striation as the walls of the meshes are equally sized and, thus, optically appear as single elements. The spines are also sculptured. In dorsal view, the carapaces are oval and laterally flattened. The greatest width is situated centrally. Internal features have not been observed in the material.

Dimensions. Length 0.65–0.95 mm, height 0.44–0.75 mm.

Occurrence. Upper Oxfordian and Lower Kimmeridgian of southern Germany.

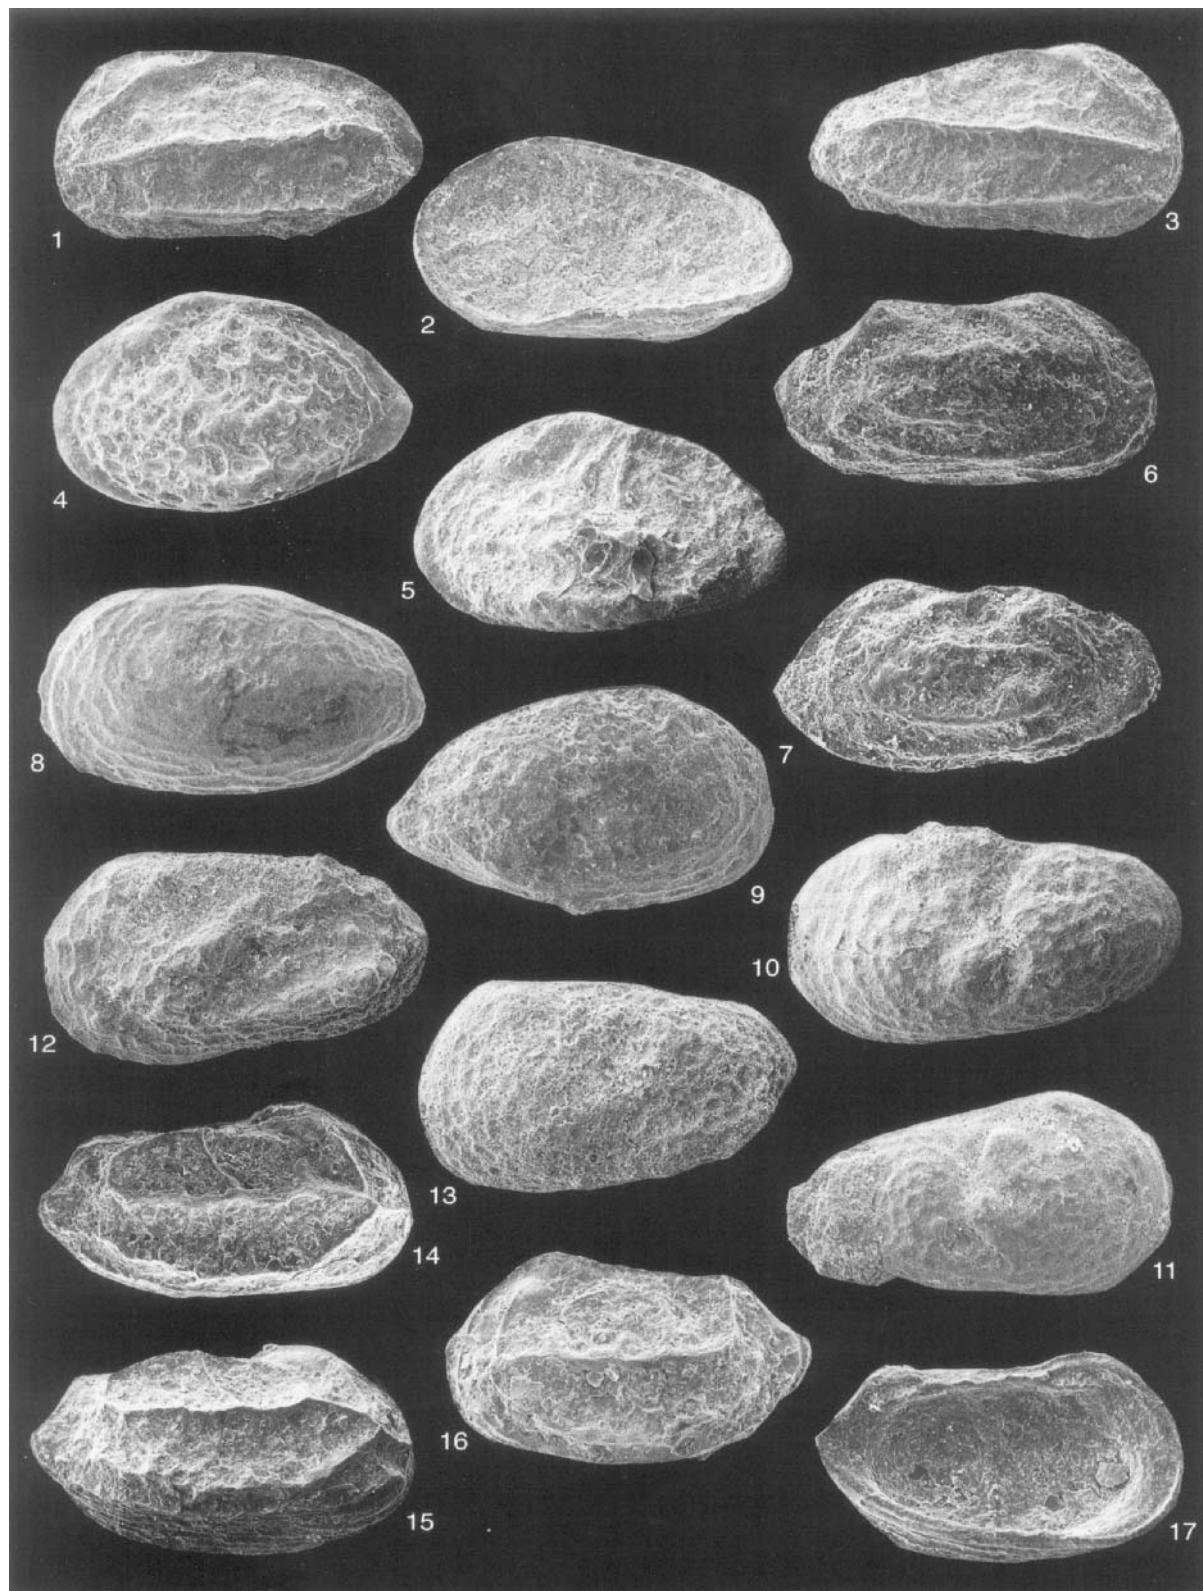

Remarks. The new species differs from the two other species of the genus *Pokornyopsis* by the regularly punctate pattern of the valve surfaces. In addition, it differs from *P. feifeli* (Triebel, 1941) by the greater distance of the two anterior spines, whereas the upper one turns more upward than in *P. feifeli* (even more than in *P. bettenstaedti* Bartenstein, 1949). The curvature of the valves is, in comparison to *P. bettenstaedti*, more flattened than in *P. feifeli*.

CONCLUSIONS

The data presented here have contributed to a new interpretation of the marine ostracod palaeobiogeography, biostratigraphy

Explanation of Plate 3

Figs 1–2. *Eocytheropteron decoratum* (Schmidt, 1954), Malm zeta 2b, Upper Solnhofener Schichten, Lower Tithonian, sample Groiss 747, quarry near Unterhartheim: 1, right valve of a male, length 0.52 mm; 2, right valve of a female, length 0.42 mm. **Figs 3–4.** *Paranotacythere* (U.) cf. *caputmortuum compactum* Bassiouni, 1974, Lower Mörnsheimer Schichten, Lower Tithonian, sample Groiss 37, Oberhartheim near Vohburg/Donau; 3, left valve, length 0.35 mm; 4, left valve, length 0.36 mm. **Fig. 5.** *Paranotacythere* sp., larval stage ?, Malm alpha, Oxfordian, sample Groiss 452, Feuerstein, left valve, length 0.23 mm; **Figs 6–8.** *Amphicythere* (A.) cf. *semisulcata* Triebel, 1954; 6, Upper Solnhofener Schichten, Lower Tithonian, sample Groiss 60, quarry X, Schöpfel/Hofstetten, south of Pfalzpaint near Eichstätt, left valve, length 0.36 mm; 7, Malm Zeta 2b, Upper Solnhofener Schichten, Lower Tithonian, sample Groiss 728, quarry Imberg near Pfalzpaint east of Eichstätt, left valve, destroyed anteroventrally, length 0.33 mm; 8, Malm Zeta 2b, Upper Solnhofener Schichten, Lower Tithonian, sample Groiss 60, quarry X, Schöpfel/Hofstetten south of Pfalzpaint near Eichstätt, left valve, destroyed in its dorsal part, length 0.34 mm; **Fig. 9.** *Hekistocythere lacrimula* (Oertli, 1959), Malm Zeta 2b, Upper Solnhofener Schichten, Lower Tithonian, sample Groiss 724b, quarry X, Schöpfel/Hofstetten south of Pfalzpaint near Eichstätt, right valve, length 0.34 mm; **Figs 10–11.** *Hekistocythere* aff. *inaequicosta* Pokorny, 1973, Malm Zeta 2b, Upper Solnhofener Schichten, Lower Tithonian; 10, sample Groiss 736, quarry near Pfalzpaint, right valve, length 0.31 mm; 11, sample Groiss 724b, quarry X, Schöpfel/Hofstetten south of Pfalzpaint near Eichstätt, left valve, length 0.29 mm; **Fig. 12.** *Macrodentina* (*Macrodentina*) cf. *dolosa* Malz, 1958, Lower Mörnsheimer Schichten, Lower Tithonian, sample Groiss 37, Oberhartheim near Vohburg a.d. phy, and palaeoclimatology during the late Jurassic in Central and Western Europe (for more details see Schudack & Schudack (1997) and Schudack (1999)).

The palaeobiogeographical development parallels a postulated cooling trend. During the Oxfordian, Kimmeridgian, Tithonian and Berriasian, a growing diversification of marine ostracod biogeography and an increase in the degree of endemism can be observed. In addition, there is a gradual southward migration of many species from the sub-boreal areas in the northwest towards the margin of the Tethys in the southeast, mainly from the Kimmeridgian into the Tithonian. For instance, most species occurring both in northern and southern Germany have been reported to appear (and also disappear) in younger strata in the south (Schudack & Schudack, 1997). Moreover, the genus *Cytherelloidea*, an indicator for relatively warm water temperatures, shifts its northern boundary of occurrence towards the south during the Kimmeridgian, Tithonian and Berriasian (Schudack, 1999). These data are in agreement with a suggested increase in the influx of cold boreal waters into Central Europe with the beginning of the Tithonian, leading to slightly colder water temperatures in the shallow seas, reduced atmospheric moisture, cool-arid conditions on the neighbouring continents, and also to the diversification of biogeographic regions as a reaction to the conflicting boreal (increased) and Tethyan (constant) influences.

Different stratigraphical ranges of most taxa in northern and southern Germany hinder ostracod-based correlations between these two areas.

ACKNOWLEDGEMENTS

The authors wish to thank Prof. Groiss (Erlangen), Dr Schairer (Munich) and Dr Urlichs (Stuttgart), who kindly made the major part of the material for this investigation available. The 'Deutsche Forschungsgemeinschaft' (Bonn) supported the research of U. Schudack by a 'Forschungsstipendium'.
