

Early Cretaceous (Neocomian-Cenomanian) Palynomorphs

B. THUSU & J. G. L. A. VAN DER EEM

Exploration Laboratory, Arabian Gulf Oil Company, PO Box 263, Benghazi, Libya, S.P.L.A.J.

INTRODUCTION

This study is primarily concerned with the Neocomian to Aptian palynomorphs recorded in selected exploration wells (See Fig. 9). In order to document a complete Early Cretaceous microfloral succession in the studied wells, a reconnaissance of Aptian to Early Cenomanian palynomorphs was also undertaken. Details of the results from this younger interval appear in a later section.

Palynomorph assemblages vary in preservation and character. To the north, sandstone, siltstone and shale deposited in shallow-marine environments, contain well-preserved assemblages of dinoflagellate cysts, pollen and spores which can be used for stage-level age determination. A majority of the samples analysed, however, contain moderate numbers of dinoflagellate cysts, but fewer miospores. The abundance of land derived detritus indicates the relatively close proximity of the shoreline. In the central and southern parts of the study area, sandstone and siltstone that are deposited in non-marine, fluvial, lacustrine or lagoonal environments show a general paucity of well-preserved palynofloras. Miospores of stratigraphic value are generally rare or absent although the majority of the samples are dominated by land derived detritus.

PALYNOmorph SUCCESSION

The majority of the wells from northern Cyrenaica show a hiatus at the Jurassic Cretaceous boundary. Late Neocomian or Aptian sediments occur immediately above Middle or early Late Jurassic sediments. Well preserved Neocomian palynomorphs were recorded in wells A1-36, B1-36, Bla-18 and A1-45. The stratigraphical ranges of palynomorphs presented on the plate explanations are local ranges and are based on the studied intervals only. A preliminary palynological zonation of Late Jurassic (Late Kimmeridgian) to Late Cretaceous (Cenomanian) is presented in Fig. 9. This zonation is based on samples dated independently on microfaunal assemblages. Further refinement of this zonation is currently in progress.

Neocomian palynomorph assemblages are moderately diverse in composition containing both dinoflagellate cysts and miospores. The dinoflagellate cysts *Muderongia simplex*, *M. staurota*, *Phoberocysta neocomica* and several species of *Canningia* and *Cyclonephelium* make their first appearance during this interval. Miospores do not dominate the assemblages although there are large

quantities of terrestrial palynodebris in the majority of the samples studied. Bisaccate pollen are generally absent. Rare but consistently present miospores include *Trilobosporites* cf. *bernissartensis*, *Matonisporites crassiangulatus*, *Equitiradites spinulosus*, *Crybelosporites* cf. *striatus* (similar to *C. striatus* but larger in size), and several species of *Pilosporites*, *Concavisporites*, *Classopollis*, *Concavissimisporites*, *Cicatricosisporites* and inaperturate pollen (*Araucariacites*, *Inaperturopollenites*). *Callialasporites* and *Exesipollenites* occur sporadically. Microfloral subdivision within the Neocomian must await the completion of the study of additional samples.

Late Neocomian to Barremian palynomorphs are well-preserved but occur only in small numbers. The dinoflagellate cysts *Aptea anaphrissa*, *Gardodinium eisenacki*, *Coronifera oceanica* and several species of *Oligosphaeridium*, in association with the miospores *Dicheiropolis etruscus*, *Stellatopollis* cf. *barghoornii*, *Appendicisporites* spp., *Retimonocolpites* spp. and "*Inaperturopollenites*" *crisopolensis* show their earliest appearance in this interval. Some species from the Early Neocomian continue as infrequent or rare components, these include *Pareodinia ceratophora*, *Prolixosphaeridium granulosum*, *Canningia* spp., *Cyclonephelium* spp., *Cicatricosisporites* spp., *Crybelosporites* cf. *striatus*, *Concavisporites* spp., *Classopollis* spp., and inaperturate pollen.

Aptian dinoflagellate cyst assemblages contain abundant representatives of *Subtilisphaera senegalensis* and *Subtilisphaera* sp. together with rare *Pseudoceratium regium* and *Cribroperidinium edwardsii*. Miospores from this interval contain the first appearance of *Afropollis* spp., *Reyrea polymorpha*, *Retitricolpites* spp., *Psilatricolpites* spp. and *Eucomiidites* sp. *Classopollis* is represented by abundant species of less than 30 microns. A number of species which disappear during this interval include "*Inaperturopollenites*" *crisopolensis*, *Stellatopollis* cf. *barghoornii*, *Callialasporites* spp., and *Appendicisporites* spp. *Ephedripites* spp., present in the Neocomian is more frequently encountered during the late Early Cretaceous. Inaperturate pollen, *Crybelosporites*, *Cicatricosisporites*, *Concavisporites* and *Pilosporites* continue as infrequent members of the assemblages.

Albian-Cenomanian palynomorph assemblages contain a number of distinctive dinoflagellate cysts including *Xenascus ceratoides*, *Cyclonephelium vanno-*

phorum and *Florentina* spp. Miospore assemblages from this interval are distinguished by the earliest appearance during the Albian of *Elaterosporites klaszii* and *Elaterocolpites castelainii* together with *Sofrepites legouxae*, tricolporate and triporate angiosperm pollen. Species of *Classopollis* less than 30 microns are replaced by larger forms of which *C. brasiliensis* is a good stratigraphic marker. Species of *Afropolis* and of the *Elaterosporites* group disappear in the Early Cenomanian but *Cicatricosporites*, *Crybelosporites*, *Retimonocolpites*, *Tricolpites* and inaperturate pollen continue to occur.

SARIR (NUBIAN) SANDSTONE

Sediments from within this unit, in the central and southern parts of the project area, where it was deposited in fluvial, lacustrine or lagoonal environments show a general paucity of well preserved palynomorphs. Miospores of stratigraphical value are generally rare. Taxa frequently present include *Cerebropollenites mesozoicus*, *Concavisporites* spp., *Classopollis* spp., *Araucariacites* sp. and rarely *Alisporites* sp. These miospores are not age diagnostic but suggest a Late Jurassic-Early Cretaceous age for the Sarir or Nubian sandstone. Samples from a limited number of wells have yielded microfloras which can be dated confidently as Neocomian-

Barremian, by the presence of *Dicheiropollis etruscus*, *Trilobosporites* sp. and *Cupressacites oxycedroides*. In one well, the rare occurrence of *Psilatricolporites* sp. and *Stellatopollis barghoornii* indicates an Aptian-Albian age.
